Abstract

In this paper we consider a quantum version of Pascal's triangle. Pascal's triangle is a well-known triangular array of numbers and when these numbers are plotted modulo 2, a fractal known as the Sierpinski triangle appears. We first prove the appearance of more general fractals when Pascal's triangle is considered modulo prime powers. The numbers in Pascal's triangle can be obtained by scaling the probabilities of the simple symmetric random walk on the line. In this paper we consider a quantum version of Pascal's triangle by replacing the random walk by the quantum walk known as the Hadamard walk. We show that when the amplitudes of the Hadamard walk are scaled to become integers and plotted modulo three, a fractal known as the Sierpinski carpet emerges and we provide a proof of this using Lucas's theorem. We furthermore give a general class of quantum walks for which this phenomenon occurs.

1 Introduction

Pascals's triangle, shown in Figure 1, exhibits many interesting properties one of which is the appearance of a fractal when the numbers are considered modulo a prime p [3, 4]. This is shown in Figure 2, and for $p = 2$ the fractal is known as the Sierpinski triangle or Sierpinski gasket. One way of obtaining the numbers in Pascal's triangle is through a random walk on a line as will be explained in Section 2. This paper explores the results of considering a similar triangle of numbers that is obtained when the 1-dimensional random walk is replaced by a 1-dimensional quantum walk. This also yields the Sierpinski triangle when the probabilities associated to the quantum walk are considered modulo 2, but more interestingly one can find another fractal known as the Sierpinski carpet hidden in the amplitudes modulo 3 which is not present in Pascal's triangle. When these quantum walk numbers are plotted modulo p, more general fractals appear.
