We show that Frenkel's integral representation of the quantum relative entropy provides a natural framework to derive continuity bounds for quantum information measures. Our main general result is a dimension-independent semi-continuity relation for the quantum relative entropy with respect to the first argument. Using it, we obtain a number of results: (1) a tight continuity relation for the conditional entropy in the case where the two states have equal marginals on the conditioning system, resolving a conjecture by Wilde in this special case; (2) a stronger version of the Fannes–Audenaert inequality on quantum entropy; (3) better estimates on the quantum capacity of approximately degradable channels; (4) an improved continuity relation for the entanglement cost; (5) general upper bounds on asymptotic transformation rates in infinite-dimensional entanglement theory; and (6) a proof of a conjecture due to Christandl, Ferrara, and Lancien on the continuity of 'filtered' relative entropy distances.

CONTENTS

I. Introduction 2

II. A semi-continuity relation for the relative entropy 4

III. Applications 6
- A. Improved Fannes–Audenaert inequality 6
- B. Improved continuity of conditional entropy 7
- C. Improved continuity of entanglement cost 11
- D. Approximate degradability 12
- E. Improved continuity of filtered entropies 15
- F. Upper bound on transformation rates in infinite dimensions 18

IV. Conclusion 19
