The European Quantum Technologies Roadmap

December 11, 2017, arXiv:1712.03773

Introduction

Max F. Riedel[1], Tommaso Calarco[1]

Within the last two decades, Quantum Technologies (QT) have made tremendous progress, moving from Noble Prize award-winning experiments on quantum physics [Nobel] into a cross-disciplinary field of applied research. Technologies are being developed now that explicitly address individual quantum states and make use of the "strange" quantum properties, such as superposition and entanglement. The field comprises four domains: Quantum Communication, where individual or entangled photons are used to transmit data in a provably secure way; Quantum Simulation, where well-controlled quantum systems are used to reproduce the behavior of other, less accessible quantum systems; Quantum Computation, which employs quantum effects to dramatically speed up certain calculations, such as number factoring; and Quantum Sensing & Metrology, where the high sensitivity of coherent quantum systems to external perturbations is exploited to enhance the performance of measurements of physical quantities.

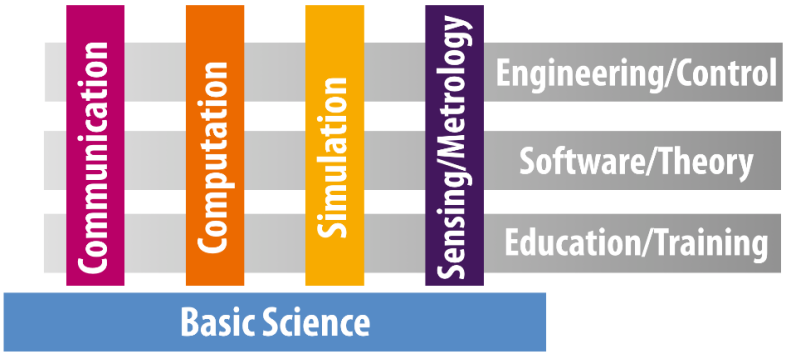

Figure 1: Structure of the research field of Quantum Technologies, according to final report of the High-Level Steering Committee on the European QT Flagship initiative [HLSC]

Recently QT have received a lot of public attention: Governments have launched large research programmes on QT, such as the Chinese programme (which includes the launch of a satellite and the instalment of a quantum key distribution link between Beijing and Shanghai) or the European Quantum Technologies Flagship initiative, summing up to several billion Euros of public funding for the field worldwide. At the same time, large multinational companies, including Google, IBM, Intel, Microsoft and Toshiba, have started to invest heavily in QT, especially in Quantum Computing and Quantum Communication. Also, a number of start-up companies were established during the last decade which successfully offer QT to specialized markets.

One success factor for the rapid advancement of QT is a well-aligned global research community with a common understanding of the challenges and goals. In Europe, this community has profited from several EC funded coordination projects, which, among other things, have coordinated the creation of a 150-page
