Random Restrictions of High-Rank Tensors and Polynomial Maps

Jop Briët[*] Davi Castro-Silva[†]

Received 23 February 2023; Published 4 November 2024

Abstract: Motivated by a problem in computational complexity, we consider the behavior of rank functions for tensors and polynomial maps under random coordinate restrictions. We show that, for a broad class of rank functions called *natural rank functions*, random coordinate restriction to a dense set will typically reduce the rank by at most a constant factor.

Key words and phrases: slice rank, analytic rank, Schmidt rank, Talagrand inequality, analysis of boolean functions

1 Introduction

Different but equivalent definitions of matrix rank have been generalized to truly different rank functions for tensors. Although they have proved useful in a variety of applications, the basic theory of these rank functions, describing for instance their interrelations and elementary properties, is still far from complete.

Without going into the definitions (which are given in Section 2), we mention a number of these rank functions to indicate some of the contexts in which they have appeared. The *slice rank* of a tensor was introduced by Tao [34, 35] to reformulate the breakthrough proof of the cap set conjecture due to Croot, Lev and Pach [8] and Ellenberg and Gijswijt [11]. Slice rank is generalized by the *partition rank*, which was introduced by Naslund to prove bounds on the size of subsets of $\mathbb{F}_q^n$ without k-right corners [27], as well as provide exponential improvements on the Erdős–Ginzburg–Ziv constant [26]. The *analytic rank* is based on a measure of equidistribution for multilinear forms associated to tensors over finite fields, and was introduced by Gowers and Wolf to study solutions to linear systems of equations in large subsets of finite vectors spaces [15]. *Geometric rank*, defined and studied by Kopparty, Moshkovitz and Zuiddam in
