A Qubit, a Coin, and an Advice String Walk Into a Relational Problem

Scott Aaronson* Harry Buhrman‡ William Kretschmer§

Abstract

Relational problems (those with many possible valid outputs) are different from decision problems, but it is easy to forget just *how* different. This paper initiates the study of FBQP/qpoly, the class of relational problems solvable in quantum polynomial-time with the help of polynomial-sized quantum advice, along with its analogues for deterministic and randomized computation (FP, FBPP) and advice (/poly, /rpoly).

Our first result is that FBQP/qpoly $\neq$ FBQP/poly, *unconditionally*, with no oracle—a striking contrast with what we know about the analogous decision classes. The proof repurposes the separation between quantum and classical one-way communication complexities due to Bar-Yossef, Jayram, and Kerenidis. We discuss how this separation raises the prospect of near-term experiments to demonstrate "quantum information supremacy," a form of quantum supremacy that would not depend on unproved complexity assumptions.

Our second result is that FBPP $\not\subset$ FP/poly—that is, *Adleman's Theorem fails for relational problems*—unless PSPACE $\subset$ NP/poly. Our proof uses IP = PSPACE and time-bounded Kolmogorov complexity. On the other hand, we show that proving FBPP $\not\subset$ FP/poly will be hard, as it implies a superpolynomial circuit lower bound for PromiseBPEXP.

We prove the following further results:

- *Unconditionally*, FP $\neq$ FBPP and FP/poly $\neq$ FBPP/poly (even when these classes are carefully defined).
- FBPP/poly = FBPP/rpoly (and likewise for FBQP). For *sampling* problems, by contrast, SampBPP/poly $\neq$ SampBPP/rpoly (and likewise for SampBQP).
